

## NEW DIFFRACTION DATA

Crystal structure of a new polymorph of iodic acid,  $\delta$ -HIO<sub>3</sub>, from powder diffractionTao Wu,<sup>1</sup> Peter Y. Zavalij,<sup>1</sup> and Michael R. Zachariah<sup>1,2,a)</sup><sup>1</sup>Department of Chemistry and Biochemistry, University of Maryland, College Park, Maryland 20742<sup>2</sup>Department of Chemical and Biochemical Engineering, University of Maryland, College Park, Maryland 20742

(Received 8 March 2017; accepted 4 July 2017)

A new polymorph of iodic acid,  $\delta$ -HIO<sub>3</sub>, synthesized via aerosol spray pyrolysis was characterized with powder X-ray diffraction and its crystal structure was solved. We find that a previously misidentified phase of I<sub>4</sub>O<sub>9</sub> hydrate is in fact a new polymorph of HIO<sub>3</sub>, which crystallizes in the orthorhombic space group  $P2_12_12_1$ . © 2017 International Centre for Diffraction Data.

Key words: iodic acids, crystal structure determination, powder diffraction, I<sub>4</sub>O<sub>9</sub> hydrate, Rietveld refinement

## I. INTRODUCTION

As one of the iodates (MIO<sub>3</sub>, where  $M = H^+$ ,  $NH_4^+$ , alkali ions, etc.), HIO<sub>3</sub> has been of interest because of its potential application as an optically non-linear material (Bergman *et al.*, 1969; Naito and Inaba, 1972; Stahl and Szafranski, 1992). The crystal structure of  $\alpha$ -phase of iodic acid was first reported in 1941, and crystallizes in the orthorhombic space group  $D_2^4$ - $P2_12_12_1$  (Rogers and Helmholz, 1941). The structure is held together by hydrogen bonds and relatively weak intermolecular iodine oxygen bonds. More recently, neutron powder diffraction at various temperatures were able to more precisely determine the position of hydrogen atoms in the crystal structure (Stahl and Szafranski, 1992). Decreased intermolecular distances and O–I–O angles of  $\alpha$ -HIO<sub>3</sub> were observed with decreasing temperature. In 2005, a new metastable, centrosymmetric polymorph of iodic acid,  $\gamma$ -HIO<sub>3</sub>, was obtained via reaction between H<sub>5</sub>IO<sub>6</sub> and Cr(ClO<sub>4</sub>)<sub>3</sub> in aqueous solution, which crystallizes in the orthorhombic space group  $Pbca$ . This phase is stabilized by hydrogen-bonded (HIO<sub>3</sub>)<sub>2</sub> dimers (Fischer and Lindsjö, 2005).

Thermal decomposition of iodic acid in air can lead to I<sub>2</sub>O<sub>5</sub> or HI<sub>3</sub>O<sub>8</sub> depending on temperature (Little *et al.*, 2015). Gas phase aerosol techniques offer a convenient route and potentially direct route for preparation of small particles with high purity, and is a method proven to be amenable and economical to scale-up (Jang *et al.*, 2013; Kaplowitz *et al.*, 2013; Zhou *et al.*, 2015; Liu *et al.*, 2016). In our investigation of aerosol route synthesis of different iodine oxides/iodic acids using HIO<sub>3</sub> as the precursor solution, we found a new polymorph could be obtained with silica gels regenerated at ~50 °C and the furnace temperature at ~210 °C (Wu *et al.*, 2017). Here, its crystal structure is reported for the first time.

## II. EXPERIMENTAL AND STRUCTURE DETERMINATION

Iodic acid ( $\alpha$ -HIO<sub>3</sub>) (99.5 wt%) purchased from Sigma-Aldrich was directly used as received. All the other

chemicals were of analytical grade and used as purchased without further treatment.

Small-sized particles of  $\delta$ -HIO<sub>3</sub> were obtained via aerosol spray pyrolysis (ASP). In general, 100 ml iodic acid solution (10 mg ml<sup>-1</sup>) were sprayed into small droplets (~1  $\mu$ m in diameter) with a homemade pressure atomizer (~35 psi pressure air) and pass through a silica-gel diffusion drier (silica gels were regenerated at ~50 °C) to remove most of the water, and are then passed through a tube furnace for chemical conversion. The tube reactor consisted of a ~1.9 cm diameter alumina tube with a heated length of ~40 cm. The furnace temperature was set at ~210 °C to obtain  $\delta$ -HIO<sub>3</sub> with a residence time of about 1 s. We find that  $\delta$ -HIO<sub>3</sub> can be obtained within a large range of temperature from 180 to 250 °C. The final product was collected on a Millipore membrane filter (0.4  $\mu$ m pore) and characterized by powder X-ray diffraction (XRD, Bruker D8 Advance using CuK $\alpha$  radiation).

The as-prepared samples were characterized by powder XRD. Diffraction pattern was measured using CuK $\alpha$  radiation in Bragg–Brentano geometry on Bruker D8 Advance powder diffractometer equipped with incident beam Soller slits, Ni  $\beta$ -filter and LynxEye position sensitive detector. Data were collected from 14 to 130°2 $\theta$  with a step size of 0.015 78° and counting time of 1 s step<sup>-1</sup> (total exposure time of 180 s step<sup>-1</sup>).

The powder pattern was indexed in the orthorhombic crystal system and reflection conditions pointed to a  $P2_12_12_1$  space-group symmetry. This phase matched a previously reported for I<sub>4</sub>O<sub>9</sub>·*x*H<sub>2</sub>O (PDF#00-045-0872) (Table I). In this case “I<sub>4</sub>O<sub>9</sub>·*x*H<sub>2</sub>O” was designated to refer to a crystal hydrate product of amorphous I<sub>4</sub>O<sub>9</sub> according to the paper that published its XRD result (Wikjörd *et al.*, 1980). However, the I<sub>4</sub>O<sub>9</sub>·*x*H<sub>2</sub>O reference provides only composition and powder pattern and motivated our consideration of determining rigorously the crystal structure.

The crystal structure was solved from the integrated intensities obtained from a LeBail full pattern decomposition by a charge flipping method using an XT program from ShelX software (Sheldrick, 2015). The crystal structure (Figure 1) was refined by Rietveld method using the Topas software

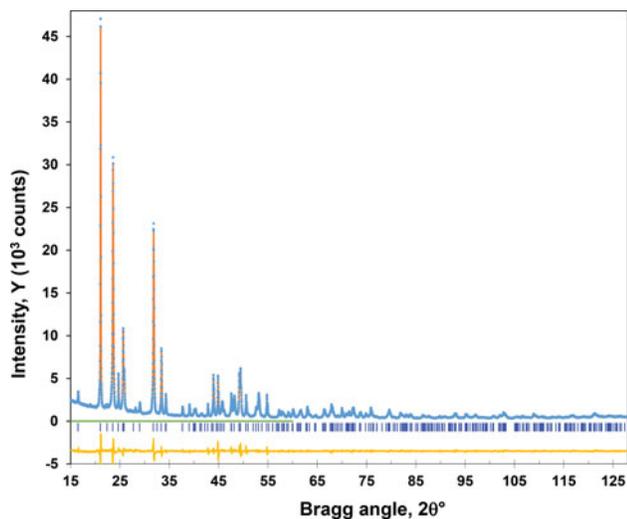

Figure 1. (Colour online) The Rietveld plot of  $\delta$ -HIO<sub>3</sub> (circles – experimental profile, solid line – calculated, their difference is shown at the bottom, vertical lines show the reflection position).

(Cheary and Coelho, 1992). The refinement revealed a presence of preferred orientation with a March–Dollase parameter of 0.75(1). Hydrogen atom was positioned from geometric considerations at the longest I–O bond along the shortest oxygen–oxygen contact line as it was observed in other structures of iodic acid. It was refined as riding on the attached O atom.

### III. DISCUSSION

This crystal structure determination shows that the actual chemical composition of I<sub>4</sub>O<sub>9</sub>·*x*H<sub>2</sub>O is HIO<sub>3</sub>, which could also be written as I<sub>4</sub>O<sub>10</sub>·2H<sub>2</sub>O. This new polymorphic modification of iodic acid is further referred as  $\delta$ -HIO<sub>3</sub> (CCDC#1526763).

Details of the crystal structure determination are shown in Table II. The atomic parameters are listed in Table III. Selected interatomic distances and bond angles of  $\delta$ -HIO<sub>3</sub>,  $\alpha$ -HIO<sub>3</sub> (Stahl and Szafranski, 1992),  $\gamma$ -HIO<sub>3</sub> (Fischer and Lindsjö, 2005), and HI<sub>3</sub>O<sub>8</sub> (Fischer, 2005) are shown in Table IV.

The  $\delta$ -HIO<sub>3</sub> crystalizes in the orthorhombic space group  $P2_12_12_1$ . Figures 2(a) and 2(b) show the crystal structure of  $\delta$ -HIO<sub>3</sub> with each iodine atom 3 coordinated with oxygen atoms (I1–O1 = 1.904, I1–O2 = 1.811, I1–O3 = 1.741), and all four atoms form trigonal pyramid with iodine atoms in the apex and three oxygen atoms in the base. One of the I–O contacts of 2.49 Å between molecules make spiral chain along the *z* direction [Figure 2(a)], and two more long I–O contacts of ~2.76 Å bind the chains in *x* and *y* directions into a three-dimensional framework [Figure 2(b)]. O1–H1...O2 hydrogen bond links HIO<sub>3</sub> molecules into a zig-zag chain along the *y*-direction, which make it unique as compared with other two polymorphs of HIO<sub>3</sub>. Two neighboring molecules are in a mirror position along with *xy*-plane. Three I–O bonds and three I...O contacts together make a distorted octahedra.

All three iodic acid structures  $\alpha$ ,  $\gamma$ , and  $\delta$  differ by packing of the HIO<sub>3</sub> molecules and therefore by arrangement of their hydrogen bonds. In  $\alpha$ -HIO<sub>3</sub>, similarly  $\delta$ -HIO<sub>3</sub> structure, hydrogen bonds link molecules into a zig-zag chains

H1	4a	0.440 511	0.444 325	0.282 977	0.92(19)

[Figure 3(a)]. However, in  $\gamma$ -HIO<sub>3</sub> hydrogen bonds form (HIO<sub>3</sub>)<sub>2</sub> pair as shown in Figure 3(b). Figure 3(c) shows that HI<sub>3</sub>O<sub>8</sub> molecule is an adduct of both HIO<sub>3</sub> and I<sub>2</sub>O<sub>5</sub> moieties that are connected by a hydrogen bond (Fischer, 2005). Interestingly, the hydrogen bond in  $\delta$ -HIO<sub>3</sub> structure is similar in length to  $\gamma$ -HIO<sub>3</sub> molecule and both are slightly shorter than that of  $\alpha$ -HIO<sub>3</sub> and HI<sub>3</sub>O<sub>8</sub> structures.

Each IO<sub>3</sub> pyramid forms three I...O intermolecular contacts in 2.5–3.1 Å range (Table III), which along with three I–O bonds form a distorted octahedra. Each I...O contact is positioned across I–O bond so that O–I...O angle deviates from linear for not more than 17°. This is true for all HIO<sub>3</sub> structures as well as HIO<sub>3</sub> and I<sub>2</sub>O<sub>5</sub> molecules in HI<sub>3</sub>O<sub>8</sub> structure. There is also correlation, at least qualitatively, between length of I–O bonds and opposite I...O contact distances: the shorter bond corresponds to longer contact and vice versa.

#### IV. CONCLUSION

A new polymorph of iodic acid,  $\delta$ -HIO<sub>3</sub>, which crystallizes in the orthorhombic space group  $P2_12_12_1$ , was obtained via a reproducible ASP method using iodic acid solution as the precursor. *Ab initio* crystal structure determination of  $\delta$ -phase reveals that previously known I<sub>4</sub>O<sub>9</sub>•*x*H<sub>2</sub>O phase is actually HIO<sub>3</sub>.
